TASK 2

PROBLEM 1

In the 1st problem you need to take input from the user however there is a problem as input() in python outputs a string so you need to turn it first into an int and to prevent unwanted inputs i forced the user to input one integer at a time using try and except then after getting the number i compare it to the current biggest and smallest number.

PROBLEM 2

In the 2nd problem i relied on the info that the number of even numbers lower or equal to a number = n//2 in which // is floor division then using that i looped an integer on that range and multiplied it by 2 and added it to the sum of all previous numbers.

PROBLEM 3

The 3rd problem teaches you a little about how to handle complex numbers in python as it requires you to get the modulus and phase of a complex number which is used alot.

PROBLEM 4

Problem 4 requires basic knowledge about if else statements and how to find if a number is odd or even using the modulo operator.

PROBLEM 5

Problem 5 becomes easy if you know about the hidden parameters in the print function specifically the “end” parameter which changes what print adds after your input to it in this case we will change it to an empty string to print all the numbers next to each other.

PROBLEM 6

In the 6th problem we are asked to reverse a sentence i put the words in a list using the fact that every 2 words are seperated by a space using indexes starting from the last space found to the current one then used reverse() to reverse the order of the words in the list then printed them by unpacking the list by typing * before the name of it in print() another method would be looping on all words in the list instead of *.

PROBLEM 7

Problem 7 you how to print in the terminal, get current date and time, find the version of linux on the device as well as whether you are using a virtual machine or not.
